Durham, ON N0G 1R0

Attention: Mr. Geoff Aitken, Manager of Public Works

Re: 2023 Annual Monitoring Report
Closed Glenelg Landfill Site

Dear Geoff:

Please find enclosed one copy of the Annual Monitoring Report (2023) for the closed Glenelg Landfill Site. On behalf of the Municipality and by way of this letter, we have submitted the report to Mr. Scott Gass, Environmental Officer at the Owen Sound District Office of the Ministry of the Environment, Conservation and Parks (MECP).

The environmental monitoring results are generally consistent with the annual monitoring results from previous years, which indicate that only minor leachate influence is being measured in the wells located within the landfill pile and that the Reasonable Use Guideline continues to be met. As recommended within the Annual Report, since the findings of the annual monitoring continue to indicate that there are no leachate related impacts, and the water quality results are generally consistent with background conditions, a reduction in the monitoring and reporting frequency has been recommended.

As requested by the MECP, a copy of the Monitoring and Screening Checklist, included in the Monitoring and Reporting for Waste Disposal Sites Groundwater and Surface Water Technical Guidance Document (MOE, 2010) has also been enclosed with the annual report. It should be noted that the attached checklist is not intended to replace the Annual Monitoring Report, but rather provide a general summary of the annual findings. Consequently, for details regarding the annual monitoring program and site operations, please refer directly to the report.

I trust that this is sufficient for your records at this time. Please do not hesitate to contact me if you have any questions, or should you wish to discuss this further.

Yours truly,

GM BLUEPLAN ENGINEERING LIMITED

Per:

Alen Bringleson, B.E.S., C.E.T.

GLENELG WASTE DISPOSAL SITE**ANNUAL MONITORING REPORT (2023)****APRIL 2024****GMBP FILE: 213088**

1. INTRODUCTION

The Glenelg Landfill Site is located approximately 8.5 kilometres east-northeast of Durham in the south Part of Lot 20, Concession 2, North of Durham Road (NDR) in the former Township of Glenelg, Municipality of West Grey, where shown on Figure 1. More specifically, it is located approximately 1.3 km north of Grey Road 4 on the west side of Baptist Church Road. According to the County mapping, the closed Glenelg Landfill Site and the associated buffer lands comprise an area of 5.32 hectares (13.12 acres), of which 0.48 hectares (1.2 acres) was approved for landfilling. The landfill site is currently maintained by the Corporation of the Municipality of West Grey.

The closed Glenelg Landfill site was in operation for approximately 33 years. Reportedly, the Township began accepting waste at the Site in December 1972 and the landfill was closed to the public in 2002, accepting only curbside pick-up until 2005. Since that time, all refuse from the Glenelg area has been diverted to the Durham and Bentinck Landfill Sites. A Provisional Certificate of Approval (CofA) for the waste disposal facility (CofA No. A261803) was issued to the Township of Glenelg by the Ministry of the Environment, Conservation and Parks (MECP) on September 29, 1985, and was revised on December 23, 1985, and August 31, 1989. An amendment to the existing CofA (August 1989) was issued on August 1, 1991, to include the requirement for the submission of an annual monitoring report by April 30th of each calendar year. A copy of the existing CofA and its amendment is provided in Appendix A.

In anticipation of the site capacity being reached in the early 2000's, a Closure Plan entitled '*Township of Glenelg Waste Disposal Site – Site Closure Plan (December 1998)*' was prepared by the Stanley Consulting Group and submitted to the MECP. According to the Closure Plan, final cover was applied to the Site in 2007 and final topsoil and seeding was completed in 2008.

The Closure Plan recommended that the semi-annual groundwater monitoring program continue for a period of at least two years following Site closure after which modifications to the monitoring program could be considered depending on monitoring results and pending MECP approval. In correspondence dated November 19, 2010, the MECP concurred with the recommendation to modify the monitoring program to once per year in the fall. In addition, the Closure Plan recommends that Annual Monitoring Reports continue to be prepared. Therefore, this annual report is being submitted to satisfy the reporting requirements outlined in the CofA and the approved Closure Plan for the Site.

2. GENERAL SITE OPERATIONS

As of 2005, the Glenelg landfill site has been closed and has not received any additional waste. The site was approved to receive domestic, commercial and 5 percent other waste limited to scrap metal, brush, wood, construction debris and demolition debris.

According to the Hydrogeologic Investigation and Plan of Development and Operation (PDO) prepared for the Glenelg Township Landfill, dated May 1985 (herein referred to as the *PDO*), the total remaining capacity for refuse and cover material was 16,100 m³ at that time. Reportedly, the landfill area filled prior to that time covered 0.17 ha with the thickness of refuse estimated to be in the range of 3 m to 4 m. Based on this information, it is estimated that an additional volume in the range of 5,000 m³ to 7,000 m³ of waste and interim cover (i.e., daily, and intermediate cover) was placed at the Site prior to that time. Based on the estimated requirement of 2,300 m³ for final cover, the capacity used for waste and interim cover between 1985 and 2005 was 13,800 m³. Therefore, the volume of waste and interim cover placed at the Glenelg Landfill is estimated to be in the range of +/- 20,000 m³.

Reportedly, the entire landfill area was capped in 2007, with final topsoil and vegetative cover being completed in 2008. Capping the landfill ensures the waste is unexposed, thus reducing infiltration and the subsequent generation of leachate. In the Closure Plan, it was proposed that '*based on the small size of the licensed area of the landfill, the future use after site closure will be practically restricted to a passive use. Potentially, the licenced area could be reforested. The buffer lands adjacent to the licensed area could be used for agricultural uses commonly found in this area of the Township with the most likely use being pastureland.*' Currently, the property continues to be left as an open space with a fence controlling site access. As per the Closure Plan, it is noted that '*before the land use can be changed to something other than waste disposal, the Township will need to submit a land use proposal for approval by the MOECC under Section 46 of the Environmental Protection Act.*'

According to the Closure Plan, the site is to be inspected on a regular basis following Site closure by the owner and/or consultant. It is recommended that the Site inspections continue to be completed annually in conjunction with the required annual groundwater.

monitoring program. The Site inspections are to include an inspection of the following:

- (i) potential settlement areas;
- (ii) the final cover and vegetation;
- (iii) site aesthetics;
- (iv) site security (i.e., fencing);
- (v) drainage; and
- (vi) rodent control.

Settlement areas causing surface ponding should be filled and covered with topsoil and vegetation to promote drainage. During the most recent annual monitoring event, no leachate seeps were observed and the ground cover system, site drainage and fencing continued to appear adequate.

3. SUMMARY OF SITE SETTING

3.1 Site Setting

The Site is surrounded by general agricultural lands and wooded areas. The topography near the site is undulating and generally slopes towards the west and northwest. There are no residential homes within 250 metres of the Site, with the nearest home situated greater than 250 metres to the east and upgradient of the Site. An additional residence is located greater than 350 m to the north of the licensed landfill area. This residence is serviced by a bedrock well screened to a depth of between 31 to 41 metres below ground surface (mbgs). The well record for this well (i.e., Tomalin well) is provided in Appendix B.

3.2 Geologic Conditions

The Site is located within the physiographic region known as the Horseshoe Moraines. The region is generally characterized by irregular, stony knobs and ridges which are composed partly of till and partly of kamey deposits, and the more or less horizontally embedded sand and gravel terraces and swampy valley floors (Chapman and Putnam, 1984). Consistent with this description, the overburden deposits in this area are classified as ice contact stratified deposits (Grey Bruce Groundwater Study, 2003) and are reported to have a thickness in the range of 20 to 30 meters.

Based on the available physiographic and topographic mapping, the Site is located within a southwest to northeast trending kame moraine deposit which itself is surrounded by spillway deposits. Review of the available well records, borehole logs and geological cross-sections previously prepared by Gamsby and Mannerow Limited (now GMBP) in conjunction with the Hydrogeologic Investigation indicate that the Site is generally underlain by sand/gravel deposits, to a depth of approximately 9 m, which are then underlain by silty/sandy gravelly till (hardpan) to an approximate depth of 30 m. Available borehole information and well construction details for the Site and copies of the cross-sections prepared in conjunction with the Hydrogeologic Investigation are provided in Appendix B.

According to the *Grey and Bruce Counties Groundwater Study* (2003), the bedrock in the area belongs to the Middle Silurian Guelph Formation which is characterized by buff to brown medium bedded dolostone. Reportedly, the bedrock in the area slopes to the west and the inferred bedrock elevation at the landfill site is in the range of +/- 400 m above sea level (masl).

3.3 Hydrogeologic Conditions

3.3.1 Surface Water

The Glenelg Landfill is situated in the Saugeen River watershed. Since the Saugeen River is situated an estimated 2 km to the northwest of the landfill, it is inferred that there is no defined watercourse for drainage to the west/northwest of the landfill area. Furthermore, based on the observed surficial sand and gravel soils noted, surface water runoff and potential ponding at the Site would be limited as water infiltrates readily into the ground.

3.3.2 Groundwater

In January 1984, seven overburden monitoring wells were installed at the Site using a track-mounted drill rig, including wells TW-1 through TW-7 to depths of between 4.6 and 10.4 mbgs. Two additional monitoring wells were installed on September 3, 1998, including TW-7A, which was intended to replace well TW-7 due to consistently 'dry' conditions; and TW-8 to monitor groundwater quality at the western compliance boundary located approximately 115 m downgradient of the licensed landfill area. Groundwater monitoring locations are presented in Figure 2.

The borehole logs/well installation records for wells TW-1 and TW-2 and a summary of the test well logs and well construction details for wells TW-1 through TW-7 are provided in Appendix B. It is noted that copies of the borehole/well logs for wells TW-7A and TW-8 were not available to GMBP at the time of report preparation.

Based on the information available, the majority of the monitoring wells are screened in the shallow overburden sand/gravel soils. The screened intervals for the shallow overburden wells located in the vicinity of the licensed landfill area, including TW-2, TW-4, and TW-6, extend to an elevation (relative) in the range between 86.7 m and 90.27 m and further downgradient at wells TW-3 and TW-5, the well screens extend to an elevation of between 84.4 m to 87.2 m. Reportedly, wells TW-1 and TW-7A monitor groundwater in the deeper overburden/hardpan unit.

Water levels are measured in all available wells during each sampling event. The measured water levels are then used to determine the direction of groundwater flow at the landfill site. The historical water level elevations, including the most recent data, are provided in Appendix C and a groundwater contour plan is provided as Figure 2. Consistent with historical results, groundwater flow within the shallow overburden is generally to the west through the shallow sand and gravel unit. A periodic radial flow pattern to the northwest and southwest is noted, particularly on the eastern portion of the Site. Groundwater levels in the deeper overburden wells TW-1 and TW-7A continue to be lower than those in the surrounding shallow overburden wells indicating that a downward gradient into the underlying hardpan unit likely exists in the vicinity of the existing fill area.

4. WATER QUALITY MONITORING

4.1 Monitoring Program

Groundwater monitoring at the Glenelg Township landfill was implemented in 1985 to evaluate the impacts landfill leachate may have on the groundwater resources in the vicinity of the Site. Although the sampling requirements, including the locations and parameters, have been revised several times, according to the CofA the monitoring program was initially to be conducted twice annually in the spring and fall. Based on recommendations in the 2009 annual report and with concurrence from the MECP provided in correspondence dated November 9, 2010 (refer to Appendix F), the sampling frequency has been reduced to once annually in the fall.

Groundwater at the Glenelg Landfill Site is currently monitored by a system of 8 monitoring wells installed throughout the landfill site and the locations of the monitoring wells are presented on Figure 2. The established monitoring program is outlined as follows:

Wells to be Sampled Once Annually in the Fall	Parameters
TW-1	
TW-2	
TW-3	pH, conductivity, hardness, alkalinity, sulphide (as H ₂ S), phenols, dissolved organic carbon (DOC), chloride, sulphate, nitrite, nitrate, ammonia, and metals (i.e., Ca, Fe, Mg, Mn, P, K and Na).
TW-4	
TW-5	
TW-6	
TW-7A	
TW-8	

The sampling event for the current monitoring year was conducted on November 22nd. Summaries of the historical groundwater analytical results and long-term trend analysis graphs are provided in Appendix D.

4.2 Sampling Procedures

For the groundwater sampling, the static groundwater level and well depth are measured in each monitoring well prior to purging three casing volumes of stagnant water from each monitoring well. GMBP personnel also check to ensure that all monitoring wells are properly secured and in compliance with O.Reg. 903. After purging, monitoring wells are allowed to recharge with fresh groundwater before sampling occurs. Groundwater purging and sampling is conducted using dedicated Waterra™ tubing and inertial-type pumps. Samples are collected in laboratory supplied containers and are kept chilled following completion of the sampling program and sent within 24 hours of the sampling event to Bureau Veritas Laboratories (BVL) in Mississauga for analysis. Samples collected for metals are placed in laboratory supplied containers without preservative and are filtered and preserved by BVL prior to analysis. The laboratory analytical report for the current monitoring year is included in Appendix E.

5. DETERMINATION OF REASONABLE USE CRITERIA FOR THE SITE

5.1 Determination of Action Levels

MOE Guideline B-7 establishes the basis for determining what constitutes the reasonable use of groundwater on properties adjacent to landfill sites. By applying the Reasonable Use Concept, the potential use of groundwater for domestic consumption will almost always provide the lowest allowable concentration limits. MOE Procedure B-7-1 provides technical details for the application of the reasonable use approach. A change in the quality of groundwater on an adjacent property, where the reasonable use is determined to be for drinking water, will be acceptable only where:

- i) Quality is not degraded by more than 50% of the difference between background concentrations and the Ontario Drinking Water Standards (ODWS) for non-health related parameters, and
- ii) Quality is not degraded by more than 25% of the difference between background concentrations and the ODWS for health-related parameters.

Background concentrations are considered to be the quality of the groundwater prior to any contamination from landfill activities.

5.2 Background Groundwater Quality

Background concentrations are considered to be the quality of the groundwater prior to any contamination from landfill activities. Historically, monitoring well TW-5 has been selected to be the background monitoring location based on the direction of shallow groundwater flow at the Site and its location relative to the fill area which results in the least potential for impacts from the landfill. It is located approximately 75 m to the southwest of the approved fill area. Historical and on-going water quality results also support the use of TW-5 as a background well as the results indicate that this monitoring location typically has the lowest concentrations of indicator parameters. Historical results, provided in Appendix D, were used to calculate average values of indicator parameters for the subsequent calculation of the RUC values. The background concentration ranges, averages, and resulting RUC values for several indicator parameters are summarized in Table 1.

The background water quality is typical of a carbonate system and is generally highly mineralized with an average background hardness of less than 300 mg/L. In general, the background chloride and sodium concentrations are typically less than 5 mg/L, sulphate concentrations are less than 10 mg/L and the background specific conductance (i.e., conductivity at 25° Celsius) is, on average, approximately 475 uS/cm.

It is noted that the hardness typically exceeds the RUC at all monitored locations. Therefore, the elevated hardness concentrations alone do not appear to be related to impacts from landfill leachate and can be attributed to the natural mineralization of the groundwater and represent background conditions.

5.3 Calculation of Objective Levels

The objective levels for several groundwater quality indicator parameters were calculated to evaluate the acceptable level of contaminant concentrations at the Site boundary. Background concentrations (C_b) are the site-specific values (discussed in the previous section). The Provincial maximum concentrations (C_r) are identified in the Ontario Drinking Water Standards. Acceptable concentrations at the site boundary (C_m) are calculated from MOECC Procedure B-7-1 using the following formula:

$$C_m = C_b + x(C_r - C_b)$$

Where:

C_m = Maximum concentration acceptable in groundwater beneath an adjacent property.

C_b = Background concentration.

C_r = Maximum concentration that should be present in groundwater for domestic consumption according to the ODWS.

x = 0.5 for non-health related parameters (AO and OG) and 0.25 for health related parameters (MAC and IMAC).

AO = Aesthetic Objective

OG = Operational Guideline

MAC = Maximum Acceptable Concentration, Parameters Related to Health

IMAC = Interim Maximum Acceptable Concentration, Parameters Related to Health

It should be noted that if background concentrations exceed the ODWS, the objective level is set at the background concentration. A summary of the average background concentrations and resulting RUC values are provided in Table 1 and a summary of the analytical results from the current monitoring year compared to the RUC and ODWS is provided in Table 2.

To determine if leachate is impacting groundwater, individual indicator parameters were evaluated in conjunction with other indicator parameters and concentration trends. Monitoring wells with elevated and stable concentrations of the identified naturally elevated constituents, that show no increases in other leachate indicator parameters, are deemed un-impacted by landfill leachate. Additionally, comparison of known leachate impacted groundwater is compared to the groundwater chemistry at locations with naturally elevated concentrations to determine if leachate contributes to the elevated concentrations measured.

6. MONITORING RESULTS AND DISCUSSION

Leachate is produced when surface water percolates down through refuse resulting in impacted water that has the potential to migrate along the surface or in the ground. Landfill derived leachate that enters into the surface water and/or groundwater is often attenuated by natural mechanisms along the water migration pathway. The attenuation of leachate can occur by dilution, biologic activity, and geochemical mechanisms. To determine the presence of (or potential impacts from) leachate, several indicator parameters are monitored, and a trend analysis is conducted to determine changes in water quality over time.

At the Glenelg Waste Disposal Site, it is anticipated that leachate production will be reduced in comparison to the leachate produced prior to closure and capping of the Site in 2007/2008. The cover material acts to limit the volume of surface water percolating down through the refuse, thereby limiting leachate production through surface water percolation.

Additionally, review of the available cross-sections and borehole logs suggests that limited waste was disposed of at this Site and that the waste was likely placed above the water table. Therefore, the production of leachate by the migration of groundwater through the bottom of the refuse pile is unlikely.

The following sections discuss the potential impacts to groundwater on-site and leaving the property boundaries in reference to compliance with the RUC. The groundwater quality results for the current monitoring year are summarized in Table 2. Historical groundwater sampling results and graphical trends of indicator parameters are included in Appendix D.

It should be noted that, consistent with groundwater flowing through carbonate-rich soils, hardness concentrations consistently exceed the ODWS operational guidelines. Therefore, references to hardness exceedances are only made where the concentrations are significantly higher than those measured in the background well, such as at wells TW-2 and TW-4.

6.1 Groundwater Quality in Proximity to the Landfill Footprint

6.1.1 Shallow Overburden

Groundwater quality in the vicinity of the approved fill area is measured in the shallow overburden aquifer at monitoring wells TW-2, TW-4, and TW-6, where shown on Figure 2. Similar to the background well TW-5, these wells are screened within the sand and gravel unit approximately four to nine meters below ground surface (mbgs).

Test well TW-2 monitors groundwater quality directly downgradient of the fill area and within approximately 5 meters of the limit of placed waste. TW-2 is considered a near-source well and this monitoring location represents leachate impacted groundwater quality at the Site. An evaluation of the historical analytical results indicates that the primary leachate indicator parameters for the Site include conductivity, alkalinity, hardness, chloride, sulphate and to a lesser degree, DOC, iron, potassium, and manganese. Consistent with historical results, RUC exceedances for alkalinity, hardness, iron, and manganese were noted. Review of the groundwater quality trend graph provided in Appendix D indicates that since the cessation of landfill activities at the Site and the subsequent closure of the fill area (i.e., 2007/2008), the leachate indicator concentrations have been stable to decreasing at this monitoring location. Of particular note, the chloride concentrations which historically ranged from 50 to up to 350 mg/L have decreased significantly, remaining below 10 mg/L since 2008. This chloride trend, combined with the overall analytical results at this near-source monitoring well, suggests that the landfill closure and capping operations have effectively reduced the level of groundwater infiltration and subsequent leachate generation at the Site.

Based on the periodic radial flow pattern observed on the eastern portion of the Site, monitoring wells TW-4 and TW-6 are inferred to be located cross-gradient to downgradient of the fill area. TW-4 is situated to the north and within 15 meters of the limit of placed waste and TW-6 is located closer to the landfill footprint, approximately 5 meters to the south. No sample could be collected from TW-4 during the current monitoring period due to dry conditions. In the previous reporting year (2022) GMBP staff was unable to locate the monitoring well and it was later noted to be destroyed. A replacement well installation was recommended and completed in 2023. The reported concentrations of indicator parameters at TW-6 did not exceed the RUC, with the exception of hardness which is unrelated to landfill leachate. The long-term trend evaluation for leachate indicator concentrations at TW-4 indicates that concentrations are primarily stable and have remained stable for a period of over ten years (i.e., since site closure in 2007/08).

Although concentrations at TW-4 have been relatively stable, with chloride concentrations typically remaining below 15 mg/L, the concentrations measured in well TW-6 have historically been more variable, particularly during the time that the landfill site was operational (i.e., prior to 2005). However, it is noted that since 2008, concentrations have been stable to decreasing and chloride concentrations have remained below 10 mg/L. Therefore, although landfill leachate-influenced groundwater has been historically noted at these monitoring locations, recent groundwater monitoring results indicate that impacts related to landfill leachate are minor. It should be noted that TW-4 and TW-6 do not represent the water quality leaving the site as buffer lands extend to the north and south of the approved landfill footprint. Further discussion of the groundwater quality in proximity to the property boundary is provided in Section 6.2.

6.1.2 Deep Overburden

Groundwater quality in the deeper overburden aquifer is monitored at wells TW-1 and TW-7A. TW-1 is located directly downgradient of the landfill footprint in the vicinity of TW-2 and is closer to the limit of placed waste than TW-2 (i.e., the leachate characterization well in the upper overburden). TW-7A is located along the southern landfill limit in close proximity to the access road. Groundwater elevations reported for these deeper overburden monitoring locations compared to nearby shallow overburden wells indicate that a downward gradient exists in the vicinity of the landfill.

Similar to the groundwater quality noted in the leachate characterization well TW-2, during the current monitoring year the concentration of hardness, sulphide, iron, and manganese exceed the RUC at TW-1. Historically, the occurrence of several elevated parameters has been attributed to landfill leachate. A review of water quality parameters suggests that the deeper groundwater generally has somewhat differing chemical characteristics with a difference in the relative occurrence of leachate indicator parameters. At TW-1, relative to leachate impacted wells, the alkalinity, ammonia, and potassium are low, while sulphate and chloride are high, and the ratio of chloride to sodium is high.

In particular, the alkalinity is typically elevated in association with landfill leachate due to the acidic nature of leachate which causes the dissolution of carbonates. It is noted that at the monitoring locations with inferred leachate impacts influence elevated levels of alkalinity and hardness (such as TW-2). In comparison, at TW-1 the concentration of alkalinity has consistently been similar to background with a stable long-term trend. It is reasonable to expect this contrast in the relative levels of hardness and alkalinity is due to the use of calcium and/or sodium chloride salts along the roadway, which will increase dissolved calcium (directly or through cation exchange) and thus, calculated hardness. However, the addition of salt does not typically have the same level of effect on alkalinity.

In addition, a review of chloride versus sodium concentrations provides information regarding the potential source of chloride. Based on our experience with many landfills in Grey and Bruce Counties, typical with influence from road salt application, the ratio of chloride to sodium is typically in the range of 2:1 or greater. In contrast, wells showing influence from leachate typically have a ratio of chloride to sodium in the range of 1:1. At TW-1, the chloride concentration was reported to be 59 mg/L, as compared to less than 10 mg/L in all the shallow overburden wells monitored in the current monitoring period (see Figure 2). The reported sodium concentration at TW-1 is 16 mg/L and therefore, the ratio of chloride to sodium is approximately 4:1.

Review of the parameter concentration trends for well TW-1 suggests that the alkalinity is stable, but the chloride and conductivity indicator parameters have been steadily increasing (trend graph is provided in Appendix D). Therefore, the increasing trend is considered to be related to potential larger scale differences in water quality, likely associated with road salting. However, based on the historical interpretation and potential for landfill leachate influence due to downwards gradients, it is recommended that the potential for influence to the deeper overburden system continue to be assessed as part of the monitoring program.

It should also be noted that, based on the borehole log (Appendix B), TW-1 is at a depth of 10.4 mbgs within a sand and gravel silt till and some mixing of shallow groundwater quality based on the well screen location across both the deeper portion of the shallow overburden, and the upper portion of the deeper system may also be occurring. Regardless, the migration of leachate-influenced groundwater into the underlying bedrock unit and/or to the compliance boundary is not anticipated based on the well depth of 10.4 m bgs; the approximate overburden thickness of 30 m; the low permeability associated with the hardpan unit observed below the sand and gravel till; and the additional distance of approximately 130 m to the western compliance boundary.

Consistent with recent data, the current groundwater quality at well TW-7A was characterized by slightly elevated and relatively stable conductivity and chloride concentrations. The chloride concentration was reported to be 20 mg/L during the current monitoring period. Other typical leachate indicator parameter concentrations are generally stable. As per the above noted discussion, it is suspected that much of the variation in water quality at TW-7A is a result of differing water quality at depth. However, the difference is less apparent than at TW-1, which may be a result of some leachate influence, and/or a mixing of shallow groundwater quality at TW-1. Based on a long-term trend analysis at the location of TW-7A, the reported analytical concentrations have remained stable since the initial sampling events were completed in the late 1990s (i.e., a period of over twenty years).

6.2 Boundary Conditions

Since groundwater flow has been measured to be in a westerly direction since annual monitoring was initiated at the Site, the property boundaries to the north, east and south are considered to be hydraulically upgradient and/or crossgradient of the landfill footprint. Therefore, the flow of potentially leachate impacted groundwater from the landfill across these compliance boundaries is not anticipated.

Groundwater quality to the west of the landfilled area is monitored at the locations of TW-3 and TW-8, which are located approximately 70 m and 115 m downgradient of the landfill footprint, respectively. Review of the historical water quality trends for TW-3 indicates that the migration of leachate-influenced groundwater in a westerly direction occurred while the landfill Site was in operation. However, a significant decrease in the concentrations of several leachate indicator parameters since the landfill was closed (i.e., placement of final cover and topsoil) is evident. The long-term trends for selected leachate indicator parameters display stable and steadily decreasing concentrations since about 2000. The hardness and alkalinity concentrations have decreased to values close to 300 mg/L and continue the stable to slightly decreasing trend over time. Recent water quality results for TW-3 suggest that the groundwater quality continues to improve even further with concentrations remaining at background levels (i.e., the reported chloride concentration was <1.0 mg/L in the current monitoring period and the concentrations have remained below 3.0 mg/L since 2009).

TW-8 is considered to be a compliance well based on its proximity to the western compliance limit (i.e., within 30 m of the property boundary). Consistent with historical results, the long-term trend analysis depicts stable and low long-term trends for the leachate indicator parameters and the groundwater quality at this compliance well continues to be consistent with background conditions.

6.3 Water Quality Summary

At the Site, the migration of leachate-impacted groundwater into the shallow overburden aquifer in the vicinity of the fill area was evident while the Site was operational (i.e., until 2005). Historical impacts were also noted at the location of TW-3, suggesting that leachate impacted groundwater was migrating through the shallow overburden to a distance of greater than 70 m downgradient of the fill area. However, since the cessation of landfill operations in 2005 and the final closure of the Site in 2007/2008, key leachate indicator parameter concentrations have generally displayed decreasing to stable concentration trends. Furthermore, at this time chloride concentrations in the shallow overburden wells generally remain below 10 mg/L and have remained below 3.0 mg/L at the downgradient boundary wells for a period of over ten years. Therefore, although leachate impacted groundwater has historically been noted at the Site, the groundwater monitoring results since closure and capping of the Site was completed in 2007/08 indicate that impacts related to landfill leachate are minor and are only observed in the monitoring wells that are located directly at the edge of the approved landfill footprint (i.e., in the near-source wells).

Compliance with MOE Guideline B-7 is monitored further downgradient and along the western compliance boundary at the locations of TW-3 and TW-8. Based on the analytical results, there is only one groundwater exceedance of the RUC across the western boundary which is an exceedance of hardness for TW-3 and is related to the natural mineralization of the groundwater rather than impact from landfill leachate. In general, the groundwater quality in this downgradient location is generally consistent with background conditions.

Downwards hydraulic gradients have been observed in the vicinity of the landfill footprint. Groundwater quality in the deeper overburden is monitored at wells TW-1, which is immediately downgradient of the landfill, and at TW-7A, located directly upgradient of the landfill and at the limit of the landfill footprint. Historically, some elevated leachate indicator parameters have been noted at these locations as part of previous annual reports.

Based on this review, it appears that the slightly elevated parameters are likely associated with natural differences in groundwater quality between the shallow and deep systems. However, based on the downwards gradients, the potential for leachate influence is considered to exist. Based on the well depth at TW-1, (10.4 mbgs), the overburden thickness of 30 m, the relatively minor extent of leachate influence, and the additional distance of approximately 130 m to the western compliance boundary, the migration of leachate-influenced groundwater into the underlying bedrock unit and/or to the compliance boundary is not anticipated.

Based on the limited size of the landfill and since the landfill was closed in 2005, it is reasonable to expect that groundwater quality will continue to improve over time. Based on the relatively limited potential for continued impacts to groundwater quality directly beneath the landfill, the potential for future off-site impacts is considered to be low, particularly since the groundwater quality at the downgradient "boundary" monitoring wells continues to show no impacts related to the landfill.

7. CONCLUSIONS

1. As of 2005, the Glenelg landfill site, which was approved to receive domestic, commercial and 5 percent other waste limited to scrap metal, brush, wood, construction debris and demolition debris has been closed and has not received any additional refuse.
2. The volume of waste and interim cover placed at the Glenelg Landfill is estimated to be in the range of approximately 20,000 m³.
3. During completion of the onsite sampling and inspection for the current reporting period, no leachate seeps were observed, and the ground cover system, site drainage, and fencing continued to appear adequate.
4. The groundwater flow within the shallow overburden is generally to the west through the shallow sand and gravel unit. A downward gradient into the underlying hardpan unit likely exists in the vicinity of the existing fill area.
5. Compliance with the MOE Guideline B-7 criteria is monitored along the western property boundary at TW-8. Based on the analytical results, there are no groundwater exceedances of the RUC at the west property boundary related to the closed landfill and groundwater quality at this location is consistent with background conditions.
6. Based on the limited size and filling rate of the landfill, the cessation of landfilling in 2005 and site closure in 2007/2008, it is reasonable to expect that the groundwater quality will remain stable or will improve over time. Based on the relatively limited potential impacts to groundwater quality directly beneath the landfill, the potential for future off-site impacts is considered to be low, particularly since the groundwater quality along the property boundary continues to show no impacts due to the landfill.
7. The TW-4 monitoring well was replaced and installed in 2023 as per the 2022 recommendations. However, the replacement well was unable to be sampled at the time of sampling.

8. RECOMMENDATIONS

1. It is recommended that annual visual inspections of the premises and monitoring wells continue to be conducted annually in conjunction with the groundwater monitoring program.
2. Based on the monitoring data, there continues to be little to no indication of surface water or groundwater quality degradation at the site and no evidence of off-site leachate impacts. Based on the fact that the landfill has now been closed for more than fifteen years and on the long-term availability of monitoring data showing stable and decreasing long-term trends, **it is recommended that consideration be given to reducing the annual monitoring and reporting to a frequency of once every 5-years.**
3. Although a reduction in the sampling frequency is recommended, the established groundwater monitoring program should continue to be completed in the fall as outlined below:

Wells to be Sampled Once Annually in the Fall	Parameters
TW-1 TW-2 TW-3 TW-4 TW-5 TW-6 TW-7A TW-8	pH, conductivity, hardness, alkalinity, sulphide (as H ₂ S), phenols, dissolved organic carbon (DOC), chloride, sulphate, nitrite, nitrate, ammonia, and metals (i.e., Ca, Fe, Mg, Mn, P, K and Na).

4. An ongoing trend analysis of the groundwater quality at the location of TW-1 is recommended to further evaluate the ongoing analytical trends at this monitoring location.

All of which is respectfully submitted,

Attention: Mr. John S. Black, Clerk

Dear Sir:

Re: Township of Glenelg
Waste Disposal Site #A261803

Please find enclosed a Notice to amend the Certificate of Approval No. A261803 dated August 31, 1989 for the Township of Glenelg waste disposal site.

It is suggested that this Notice be carefully read in order to ensure that all conditions are met.

Should you have any questions, please call either Mr. Bill Hutchison of the Owen Sound District Office at (519) 371-2901 or myself at (416) 440-3726 at any time.

Yours truly,

D. A. McTavish
Regional Director

JFJ/lb

Township of Glenelg
R. R. #1
Markdale, Ontario
NOC 1H0

The Provisional Certificate of Approval No. A261803 dated August 31 1989 is hereby amended as follows:

The following condition and corresponding reason is added to the Provisional certificate of Approval.

4. The Township shall submit an annual report prepared by their consultant to the Owen Sound District Office, Ministry of the Environment, addressing the following requirements;;

- 1) volumes of waste received; remaining capacity and site life expectancy.
- 2) review of operating procedures, and any deficiencies therein,
- 3) the results of any surface water or ground water monitoring programs which may be initiated; and
- 4) the extent and success of the recycling program established by the town.

This report is to be submitted each year by April 30th, commencing April 30th, 1992.

The reason for this addition is to ensure that the necessary studies are completed in order to ensure the protection of the natural environment.

You may by written notice serve upon me and the Environmental Appeal Board within 15 days after receipt of this Notice, require a hearing by the Board. Section 122a of the Environmental Protection Act, as amended in 1983, provides that the Notice requiring a hearing shall state:

1. The portions of the approval or each term or condition in the approval in respect of which the hearing is required, and;
2. The grounds on which you intend to rely at the hearing in relation to each portion appealed.

In addition to these statutory requirements, the Notice should include:

3. The name of the appellant;
4. The address of the appellant;
5. The Certificate of Approval number;
6. The date of the Certificate of Approval;
7. The name of the director;
8. The municipality within which the works are located; and the Notice should be signed and dated by the appellant.

This Notice should be serviced upon:

The Secretary,
Environmental Appeal Board
112 St. Clair Avenue West
5th Floor
Toronto, Ontario
M4V 1N3

AND

The Director
Southwest Region
Ministry of the Environment
985 Adelaide Street South
London, Ontario

Under the Environmental Protection Act and the regulations and subject to the limitations thereof, this Provisional Certificate of Approval is issued to:

Aux termes de la Loi sur la protection de l'environnement et des règlements y afférents et sous réserve des restrictions qui s'y appliquent, ce Certificat provisoire d'autorisation est délivré à:

Township of Glenelg,
R. R. #1,
Markdale, Ontario.
NOC 1H0

for the use and operation of a 0.48 hectare landfilling site within
a total site area of approximately 4.8
hectares

all in accordance with the following plans and specifications:

Hydrogeologic Investigation and Plan of Development and
Operation Glenelg Township Landfill dated May 1985.

Located: Part of Lots 19 and 20, Concession 2,
North of the Durham Road,
Township of Glenelg, County of Grey and
Being Parts 1 and 2 on Deposited Plan No. 17R-1872

which includes the use of the site only for the disposal of the
following categories of waste (NOTE: Use of the site for additional
categories of wastes requires a new application and amendments to
the Provisional Certificate of Approval)

Domestic, commercial and 5% other, limited to scrap metal,
brush, wood, construction debris and demolition debris.

and subject to the following conditions:

1. No waste other than segregated brush, lumber and clean wood is to be burned at the site and only under conditions that prevent off site impact.
2. Access to the waste disposal site by the public and other unauthorized personnel is prohibited when burning is carried out.
3. No burning is to be carried out unless supervision is being provided by the operating authority at all times.

**APPENDIX D:
SUMMARY OF GROUNDWATER ANALYTICAL RESULTS
(TABLES & GRAPHS)**

**GLENELG WASTE DISPOSAL SITE
HISTORIC GROUNDWATER QUALITY RESULTS NOTES**

Notes:

1. ODWS= Ontario Drinking Water Standards (June 2003, Revised June 2006)
2. - = No Value
3. ND = Not Detected; NA = Not Applicable
4. * indicates outlier interpreted as sample or lab error.
5. Data prior to 2013 is from the Annual Monitoring Report (2012), Genivar.
6. Results presented in mg/L unless otherwise specified; conductivity in $\mu\text{S}/\text{cm}$ = microsiemens per centimeter; pH = Unitless.
7. Values in bold represent results greater than the ODWS
8. IMAC indicates an interim maximum acceptable concentration.
9. AO indicates an aesthetic objective, not health related.
10. OG indicates an operational guideline, not health related.
11. c indicates that the guideline applies to water at the point of consumption.
12. d, where nitrate and nitrite are present the total of the two should not exceed 10 mg/L.
13. < indicates parameter not detected above method detection limit.
14. DOC = Dissolved Organic Carbon
- 15 . Only samples collected are presented

Remarks:

Bureau Veritas is accredited to ISO/IEC 17025 for specific parameters on scopes of accreditation. Unless otherwise noted, procedures used by Bureau Veritas are based upon recognized Provincial, Federal or US method compendia such as CCME, MELCCFP, EPA, APHA.

All work recorded herein has been done in accordance with procedures and practices ordinarily exercised by professionals in Bureau Veritas' profession

CERTIFICATE OF ANALYSIS

BUREAU VERITAS JOB #: C3AI806

Received: 2023/11/23, 09:42

using accepted testing methodologies, quality assurance and quality control procedures (except where otherwise agreed by the client and Bureau Veritas in writing). All data is in statistical control and has met quality control and method performance criteria unless otherwise noted. All method blanks are reported; unless indicated otherwise, associated sample data are not blank corrected. Where applicable, unless otherwise noted, Measurement Uncertainty has not been accounted for when stating conformity to the referenced standard.

Bureau Veritas liability is limited to the actual cost of the requested analyses, unless otherwise agreed in writing. There is no other warranty expressed or implied. Bureau Veritas has been retained to provide analysis of samples provided by the Client using the testing methodology referenced in this report. Interpretation and use of test results are the sole responsibility of the Client and are not within the scope of services provided by Bureau Veritas, unless otherwise agreed in writing. Bureau Veritas is not responsible for the accuracy or any data impacts, that result from the information provided by the customer or their agent.

Solid sample results, except biota, are based on dry weight unless otherwise indicated. Organic analyses are not recovery corrected except for isotope dilution methods.

Results relate to samples tested. When sampling is not conducted by Bureau Veritas, results relate to the supplied samples tested.

This Certificate shall not be reproduced except in full, without the written approval of the laboratory.

Reference Method suffix "m" indicates test methods incorporate validated modifications from specific reference methods to improve performance.

* RPDs calculated using raw data. The rounding of final results may result in the apparent difference.

(1) Dissolved Organic Carbon (DOC) present in the sample should be considered as non-purgeable DOC.

(2) Values for calculated parameters may not appear to add up due to rounding of raw data and significant figures.

=====

This report has been generated and distributed using a secure automated process.

Bureau Veritas has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per ISO/IEC 17025, signing the reports.

For Service Group specific validation, please refer to the Validation Signatures page if included, otherwise available by request. For Department specific Analyst/Supervisor validation names, please refer to the Test Summary section if included, otherwise available by request. This report is authorized by Rodney Major, General Manager responsible for Ontario Environmental laboratory operations.

N/A = Not Applicable

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

NC (Matrix Spike): The recovery in the matrix spike was not calculated. The relative difference between the concentration in the parent sample and the spike amount was too small to permit a reliable recovery calculation (matrix spike concentration was less than the native sample concentration)

NC (Duplicate RPD): The duplicate RPD was not calculated. The concentration in the sample and/or duplicate was too low to permit a reliable RPD calculation (absolute difference <= 2x RDL).

(1) Matrix Spike exceeds acceptance limits, probable matrix interference

RECEIVED
NOV 22 2010

Mr. Ken Gould
Municipality of West Grey
402813 Grey Rd. 4
RR 2
Durham, ON, N0G 1R0

Dear Mr. Gould,

RE: Glenelg Landfill 2009 Annual Monitoring Report

We have received a copy of the report titled "Annual Monitoring Report - 2009 Glenelg Landfill Site, Municipality of West Grey" prepared by Genivar Consultants and dated April 2010. Our Regional Hydrogeologist reviewed the report and comments are provided below.

The Glenelg Landfill site is 0.45 hectares (1 acre) in size and is located on Part Lot 20 Concession 2, North Durham Road (NDR) in the former Township of Glenelg. Landfilling of waste ceased in 2005 with formal closure of the site occurring in 2006. Subsequent capping of the site occurred in 2007. Shallow groundwater is located approximately 5 metres below the landfill mound. Geology in the vicinity is silty sand and gravels. The groundwater monitoring program for the site has over 20 years of water quality data from which to assess landfill related impacts.

The Report concludes the landfill is not having adverse impacts on the surrounding environment based on data from the groundwater monitoring network in place. In addition, by way of a property boundary impact assessment the site was determined to be compliant with the Ministry of the Environment Guideline (MOE) B-7 Reasonable Use Concept (RUC) for Groundwater Management at property boundaries.

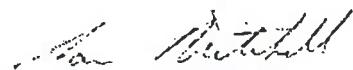

Our Regional Hydrogeologist concurs with the groundwater findings of the Report, as supported by the extensive database. Being compliant with the Ministry's RUC means that all potential landfill related impacts migrating in groundwater from beneath the landfill mound towards the property boundary monitoring wells have been attenuated over that distance to meet Ministry drinking water standards. All groundwater flowing beyond the property boundary monitoring wells would, therefore, no longer reflect the impacts of the

landfill at adverse leachate concentrations. As the site is permanently closed and has not accepted waste in over 5 years, this groundwater status is expected to continue.

Our Regional Hydrogeologist also supports the balance of the conclusions and recommendations, as presented in the Report. Based on the results of the Report, the recommendation to reduce the groundwater monitoring program from twice a year to once a year in the Fall, is justifiable from a groundwater perspective.

If you have any questions concerning this letter, please contact the undersigned at (519) 371-6191.

Yours truly,

Ian Mitchell, P.Eng.
District Engineer
Owen Sound District Office
